18

19 **Additional methods and results: inclusion of competition.**

20

21 As introduced in the main text, in the following paragraphs we explore how under
22 simplified assumptions the inclusion of interspecific competition, in conjunction with
23 treatment effects and taxonomic resolution, affects biodiversity indices. We analyse
24 situations where only species within a genus compete for the same resources because they
25 are ecologically similar, and that both species are equal competitors. Throughout this
26 study, we treat only this (restrictive) case of within genus competition, for simplicity
27 referred to as competition, well aware that competition often also takes place among
28 distantly related species (Marquet 1990), with different competitive abilities involved that
29 may additionally vary over time (Connell 1983).

30

31 **Methods**

32 To study the effect of competition, we apply the concept of press perturbation (Bender
33 1984). For the simple situation here of one genus with two competing species, this implies
34 that when one species is reduced in abundance due to treatment, the other species shifts to
35 a higher equilibrium value.

36 We apply a simple Lotka-Volterra competition model to calculate the modified
37 equilibrium densities. The scaled system without treatment for two equally good
38 competitor species is given by eq. 11:

39

$$\begin{aligned}\frac{dX}{dt} &= 1 - (X + \gamma Y) \\ \frac{dY}{dt} &= 1 - (Y + \gamma X)\end{aligned}\tag{11}$$

40

41 Without treatment both species would attain the same equilibrium value $E = 1/(\gamma + 1)$.
 42 However, in case one competing species is affected by treatment, its abundance is kept at
 43 $E_t = \alpha E$, whereas the congeneric species will reach the new equilibrium value $E' = 1 -$
 44 $\alpha\gamma/(\gamma + 1)$. For such a competitive system to have a stable non-trivial equilibrium point,
 45 all interaction strength parameters must be smaller than 1. Nonetheless, to simplify the
 46 following equations, we chose parameter values of 1. In dynamical terms this turns the
 47 equilibrium point into a half-stable one, in this case $E_t = \alpha/2$ and $E' = 1 - \alpha/2$. By
 48 choosing a carrying capacity of $K = 2n$, and noting that E_t and E' represent proportions,
 49 the equilibrium abundances are given by $n_t = \alpha n$, and $n' = n(2 - \alpha)$.

50 Next, we derive the diversity index when all species are determined at species
 51 level. Three cases have to be considered: a) no species in a genus is affected by treatment,
 52 b) both species are affected by treatment, and c) only one of the species is affected by
 53 treatment. For case c), both equilibria n_t and n' are relevant, for case a) none of them is
 54 relevant, and for case b) the same equilibrium n_t is relevant for both species. The total
 55 number of individuals is $\bar{N} = (S(1 - \delta) - S\delta(1 - \psi))n + Sn\alpha\delta\psi + Sn\alpha\delta(1 - \psi) +$
 56 $Sn(2 - \alpha)\delta(1 - \psi)$, which can be simplified to $\bar{N} = N(1 + \delta\psi(\alpha - 1))$. For the latter
 57 case we write $\bar{N} = Nh$, also used for eq. 16. Thus, the equation for the Simpson-index
 58 with competition includes on the right side, from left to right (eq. 12): (i) unaffected
 59 species (without competition), (ii) affected species (without competition), (iii) affected
 60 species (with competition), and (iv) unaffected species (with competition).

61

$$\begin{aligned}
 & {}_{t+c}^{0L}\lambda \\
 &= (S(1-\delta) - S\delta(1-\psi)) \left(\frac{n}{\bar{N}}\right)^2 + S\delta\psi \left(\frac{\alpha n}{\bar{N}}\right)^2 + S\delta(1-\psi) \left(\frac{\alpha n}{\bar{N}}\right)^2 \\
 &+ S\delta(1-\psi) \left(\frac{(2-\alpha)n}{\bar{N}}\right)^2
 \end{aligned} \tag{12}$$

62

63 Rearranging and simplifying eq. 12 leads to eq. 13:

64

$${}_{t+c}^{0L}\lambda = \lambda_0 \left(\frac{1 + \delta(\alpha^2 - 1)}{h^2} + \frac{\delta(1-\psi)((2-\alpha)^2 - 1)}{h^2} \right) \tag{13}$$

65

66 If $\psi = 1$, then ${}_{t+c}^{0L}\lambda$ reduces to ${}^0L_t\lambda$. If $\psi = 0$, eq. 13 reduces to:

67

$${}_{t+c}^{0L}\lambda_{\psi=0} = \lambda_0(1 + 2\delta(\alpha - 1)^2) \tag{14}$$

68

69 The last case we discuss includes competition *and* taxonomic resolution. Here
 70 again we make the assumption of a strong phylogenetic signal (see explanation for eq. 9
 71 above), but only in part. Obviously, competition effects are only expressed if only one (of
 72 two) species is affected by treatment, so the strong assumption does not make sense at this
 73 level. However, for the binning process the reduced abundance of an affected species plus
 74 the increased abundance of its competitive congener result in the same total abundance at
 75 genus level as for two unaffected species taken together, namely $2n$. The above-mentioned
 76 partial assumption of a strong phylogenetic signal thus means that for all genera whose
 77 species are *not* competitors we make the strong assumption: both species are or are not
 78 affected by treatment.

79 The equation for the Simpson-index including competition and taxonomic
 80 resolution includes on the right side, from left to right (eq. 15), with \bar{N} as defined for eq.
 81 12: (i) unaffected species at species level, (ii) unaffected species at the higher level, (iii)
 82 affected species (without competition) at species level, (iv) affected species (without
 83 competition) at a higher level, (v) unaffected species (with competition) at species level,
 84 (vi) affected species (with competition) at species level, and (vii) mixed
 85 affected/unaffected species (with competition) at a higher level.

86

$$\begin{aligned}
 & \frac{1^L}{t+c} \lambda \\
 &= (S(1-\delta) - S\delta(1-\psi) - b2^u) \left(\frac{n}{\bar{N}}\right)^2 + b \left(\frac{2^u n}{\bar{N}}\right)^2 + (S\delta\psi - b_\delta 2^u) \left(\frac{\alpha n}{\bar{N}}\right)^2 \\
 &+ b_\delta \left(\frac{2^u \alpha n}{\bar{N}}\right)^2 + (S\delta(1-\psi) - b_\psi 2^{u-1}) \left(\frac{\alpha n}{\bar{N}}\right)^2 \\
 &+ (S\delta(1-\psi) - b_\psi 2^{u-1}) \left(\frac{(2-\alpha)n}{\bar{N}}\right)^2 + b_\psi \left(\frac{2^u n}{\bar{N}}\right)^2
 \end{aligned} \tag{15}$$

87

88 Rearranging and simplifying eq. 15 leads to eq. 16:

$$\begin{aligned}
 & \frac{1^L}{t+c} \lambda \\
 &= \lambda_0 \left(\frac{1 + \delta(\alpha^2 - 1)}{h^2} + \frac{\delta(1-\psi)((2-\alpha)^2 - 1)}{h^2} + \frac{(b + \alpha^2 b_\delta) 2^{u-d} (2^u - 1)}{h^2} \right. \\
 & \left. + \frac{b_\psi 2^{u-d} (2^u - 2(\alpha - 1) - \alpha^2)}{h^2} \right)
 \end{aligned} \tag{16}$$

89

90 If $\psi = 0$, and hence $b_\delta = 0$, meaning that all affected species have a congener that is not
 91 affected, eq. 16 reduces to:

92

$$\begin{aligned} & \frac{1^L}{t+c} \lambda_{\psi=0} \\ &= \lambda_0 \left(1 + 2\delta(\alpha - 1)^2 + 2^{u-d}(2^u - 1) \left(b + \frac{b_{\psi}(2^u - 2(\alpha - 1) - \alpha^2)}{(2^u - 1)} \right) \right) \end{aligned} \quad (17)$$

93

94 Results

95 All Specimens Determined to Species Level

96 Fig. A1a shows the effect of treatment alone (same as Fig. 3a) and Fig. A1b the effect of
 97 treatment in combination with competition, i.e. $\frac{0^L}{t+c} \lambda^{-1} - \lambda_0^{-1}$ (eqs. 13 & 4), both as
 98 contour plots with species mortality (δ) and individual survival (α) as axes. δ in Fig. A1b
 99 stops at 0.5 because we chose $\psi = 0$, i.e. every genus contained one affected species and
 100 one unaffected congener. For all combinations of δ and α the inclusion of competition
 101 (Fig. A1b) always leads to a greater reduction in biodiversity, except for all α with $\delta = 0$
 102 and for all δ with $\alpha = 0$.

103

104

105 **Fig. A1. (a)** Contour plots of the reduction in diversity as a function of treatment (t) when
 106 all specimens are determined to species level, and **(b)** for the combined effect of
 107 t[reatment] and c[ompetition within genus] (t+c). In (a) an additional contour plot is
 108 overlaid showing the proportional reduction in total number of individuals. Species
 109 mortality (δ) is on the x-axis and individual survival α on the y-axis.

Taxonomic Resolution

Fig. A2 shows the reduction in diversity when (i) including treatment (left column contour-plots a - c), and (ii) for the combined effects of treatment and competition (right column contour-plots d - f); left column panels are the same as in Fig. 5 (left column). The corresponding eqs. 10 and 13 allow including taxa at *one* higher taxonomic level that (i) contain unaffected species (parameter b), (ii) contain affected species (b_δ), or (iii) contain species with competition (b_ψ), alone or in combination. Fig. A3 shows the same constellation, but with all higher taxa at family level. To permit direct comparison between taxonomic levels, in Fig. A3 we always used half of the values used at genus level (Fig. A2), as in our symmetrical tree (Fig. 1b) two genera bin into one family. For illustrative purposes we chose the particular combinations leading to the three contour-plots in each column of Figs. A2 & A3. If b_δ and b_ψ are greater than 0, then the proportion of species affected $\delta > 0$ is a function of these taxa and their taxonomic level (Table 1). Therefore the plotted values in Fig. A2b,c,e,f and A3b,c,e,f start at $\delta > 0$ (x-axis).

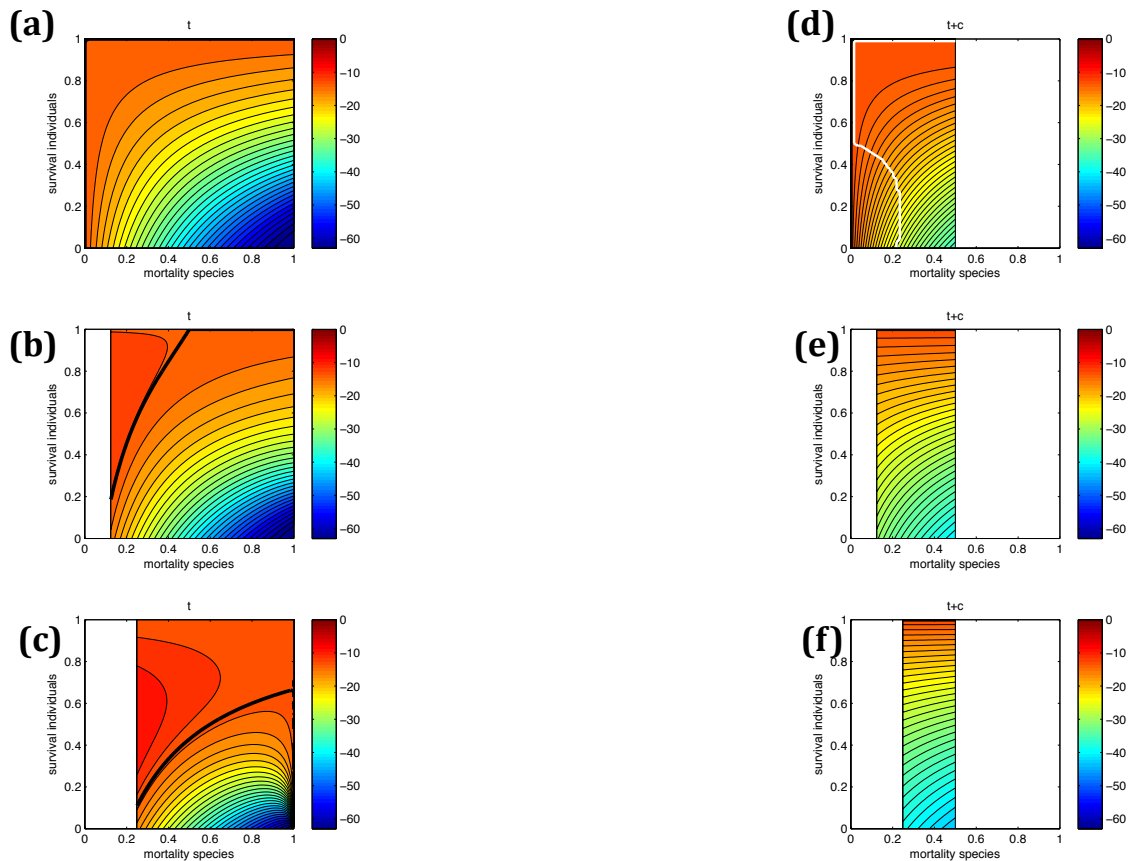

Fig. A2. Contour plots of the reduction in diversity as a function of taxonomic resolution and treatment (left column), and for the combined effects of treatment (t), taxonomic resolution, and within genus competition (right column: t+c), with all higher taxa (here 8) at genus level. Species mortality (δ) is on the x-axis and individual survival (α) on the y-axis. Parameter combinations: **(a,d)** all higher taxa unaffected: $b = 8$, $b_\delta = b_\psi = 0$; **(b,e)** four taxa affected ($b = 4$) and four unaffected ($b_\delta = b_\psi = 4$); **(c,f)** all taxa affected: $b = 0$, $b_\delta = b_\psi = 8$. Solid black lines: contour levels when only considering taxonomic resolution effects. Solid white lines: reduction when treatment (in the left column, same row) equals that with treatment and competition (in the right column). If b_δ and b_ψ are greater than 0, then the proportion of species affected $\delta > 0$ is a function of these taxa and their taxonomic level (Table 1); therefore the plotted values in Figure A3b,c,e,f start at $\delta > 0$ (x-axis).

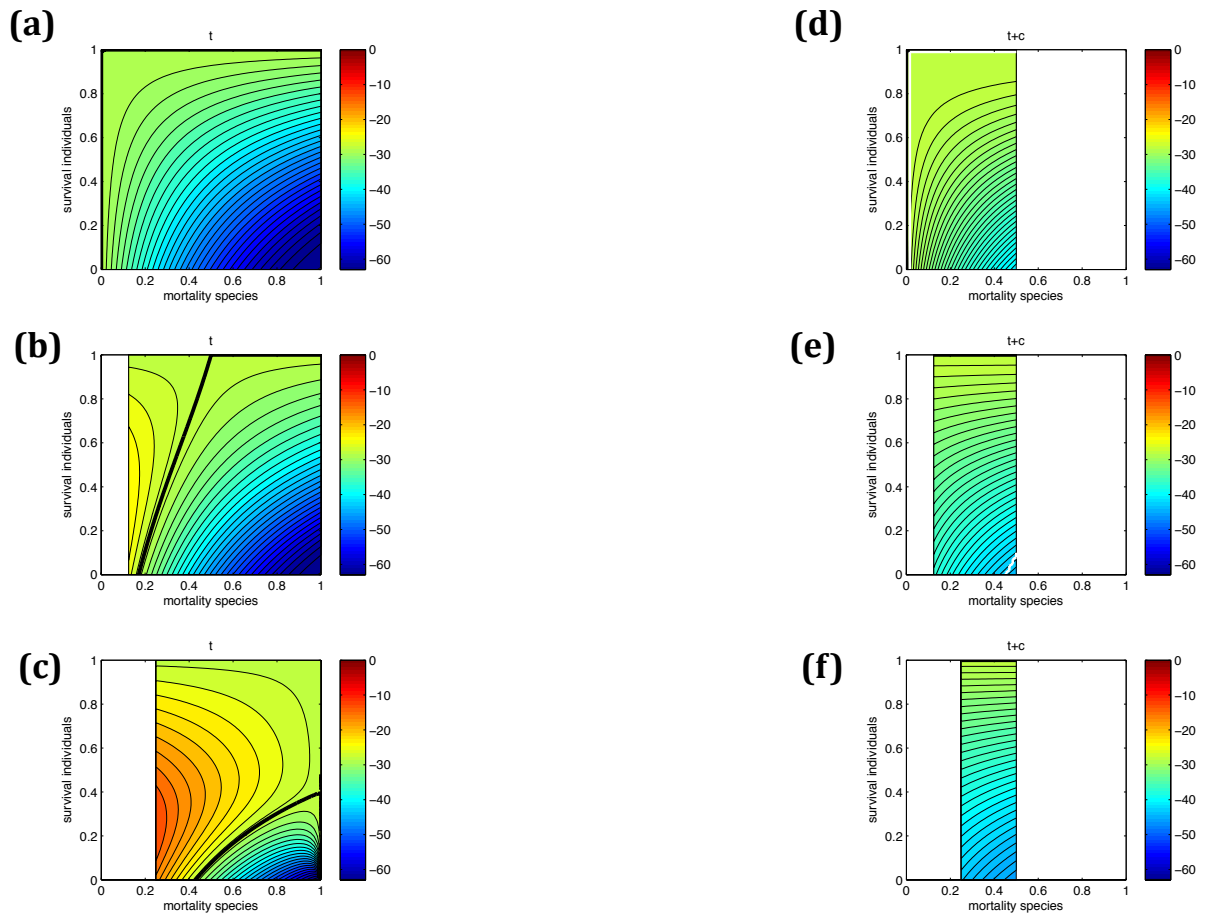

Fig. A3. Contour plots of the reduction in diversity as a function of taxonomic resolution and treatment (left column), and for the combined effects of treatment (t), taxonomic resolution, and within genus competition (right column: t+c), with all higher taxa (here 4) at genus level. Species mortality (δ) is on the x-axis and individual survival (α) on the y-axis. Parameter combinations: **(a,d)** all higher taxa unaffected: $b = 4$, $b_\delta = b_\psi = 0$; **(b,e)** two taxa affected ($b = 2$) and two unaffected ($b_\delta = b_\psi = 2$); **(c,f)** all taxa affected: $b = 0$, $b_\delta = b_\psi = 4$. Solid black lines: contour levels when only considering taxonomic resolution effects. Solid white lines: reduction when treatment (in the left column, same row) equals that with treatment and competition (in the right column). If b_δ and b_ψ are greater than 0, then the proportion of species affected $\delta > 0$ is a function of these taxa and their taxonomic level (Table 1); therefore the plotted values in Figure A3b,c,e,f start at $\delta > 0$ (x-axis).

Figures A2 & A3 show three main responses of our biodiversity measure resulting from including competition. (1) For most treatment combinations the additional inclusion of competition leads to a more pronounced decrease in diversity, except when higher taxa contain only unaffected species (top row in Figs. A2 & A3). In this case either all combinations including competition show less reduction in biodiversity (Fig. A3d, family level), or all combinations in the area right of the white line show less reduction (Fig. A2d, genus level). The second exception is the small fraction of combinations in Fig. A3e delimited by the white line (bottom-right corner). (2) The thick black contour lines in Figs. A2 & A3 delineate the sole effect of taxonomic resolution with 8 (4) taxa at the genus (family) level. From top to bottom in Figs. A2a-c, a decrease in unaffected (b) and corresponding increase in affected taxa (b_δ) at the higher taxonomic level leads to less reduction in biodiversity for an increasing set of combinations of α and δ (towards the upper left in Figs. A2a-c). This effect is even more pronounced at the family level compared to the genus level (cf. Fig. A2a-c & A3a-c), and does not show in Figs. A2d-f and Figs. A3d-f when competition is additionally included (b_ψ). (3) When augmenting the number of taxa at the higher taxonomic level that include either affected species or species suffering from competition (i.e. from top to bottom), the results in the left and right columns of Figs. A2 & A3 increasingly diverge. In the left column (without competition) the aforementioned introduces strong nonlinearities, and overall diminishes the reduction in diversity (compare contour plot colour bars with the same scale). This effect is absent in the right column when competition is additionally included.

Discussion

When not considering taxonomic resolution, adding competition led to additional reductions in diversity beyond those exerted by treatment (Fig. A1). This results because

180 competition, as defined in this study, introduces within-genus variation, and consequently
181 overall unevenness. Although in our analytical approach competition can be varied by
182 changing the parameter ψ , we only showed results for $\psi = 0$, the situation when every
183 genus contains one unaffected and one affected species. This implies that, as every affected
184 species is reduced in abundance by the treatment, the corresponding competing species
185 rises in abundance in a compensatory way due to competitive release, thus resulting in a
186 less even community abundance distribution with a lower diversity index compared to the
187 equivalent situation without competition ($\psi = 1$).

188 When treatment and taxonomic resolution effects are further combined with
189 competition, the overall picture gets more varied and rather difficult to explain without
190 resorting to the analysis of the underlying equations (avoided here). First, when all higher
191 taxa comprise only unaffected species, the addition of competition attenuates the diversity
192 reduction for some (genus-level: Fig. A2a vs. d) or all parameter combinations (family-
193 level: Fig. A3a vs. d). However, when the number of unaffected taxa at the higher level
194 decreases by including more affected taxa (Figs. A2b,c,e,f & A3b,c,e,f), competition
195 almost always further reduces biodiversity (exception depicted in Fig. S3e). Second,
196 compared to the situation with ideal taxonomic resolution (solid black contour lines in
197 Figs. A2 & A3), adding competition prevents the above-mentioned smaller diversity
198 reduction due to treatment (compare red shadings above the black line in Fig. A2b,c to Fig.
199 A2e,f, where the black line is situated at the top of the graph at 100% individual survival).
200 Third, no strong nonlinearities appear when introducing competition (in fact, they
201 disappear: compare right and left columns in Figs. A2 & A3). This occurs because the
202 combined abundances of two congeners experiencing competition, with only one being
203 affected by treatment, result in the same total abundance as two unaffected congeners.
204 Thus, augmenting the number of taxa at the higher level including competition has

qualitatively similar effects as when substituting higher unaffected taxa with affected ones (Figs. A2 & A3, top to bottom). Hence, a negative effect of a treatment on one species will remain undetected in practice if species are binned because of compensatory competitive replacement by the closely related unaffected species. Nevertheless, addition of within-genus competition as treated in this study in general attenuates possible effects of treatment mortality on diversity, potentially also disabling strong nonlinearities.
