# Supplemental Material for Zhao et al., "A Novel Hybrid Combination Optimization Algorithm Based on Search Area Segmentation and Fast Fourier Transform," Engineering Optimization, 2018. 

## S1. Convergence analysis of HSAS/FFT

Convergence of the HSAS/FFT is proved in this part. The evolutionary process of HSAS/FFT can be regarded as a series of the stochastic sequence. The stochastic sequence is used to analyse the process of HSAS/FFT. And the convergence of the HSAS/FFT is proved by the criterion in (Peng and Xie 2012). Meanwhile, two theorems are presented to prove the convergence of HSAS/FFT.

Definition 1. $S=I^{D}$ is the search space, and $f: S \rightarrow I^{+}$is fitness. $I$ is the set of spaces divided by period that frequency corresponds to, $a^{*}$ denotes the global optimal area. Then the processing of the divided area which is searched by HSAS/FFT can be described as $\left\{a \in I \mid f\left(a^{*}\right)=\right.$ $\min f(a)\}$.

Lemma 1. (Peng and Xie 2012) if a sequence is monotonous and no ascending as well as has lower bound, it must possess a limit.

Lemma 2. (Peng and Xie 2012) if a sequence is monotonous and no ascending as well as has lower bound, its subsequence must possess a limit.

Theorem 1. The direction of the population movement is monotonous, that is $f(A(n+$ 1) $) \leq f(A(n))$, thus the sequence $\left\{f\left(a^{(n)}\right)\right\}$ is monotonous and no ascending as well as has lower bound.

Theorem 2. HSAS/FFT can converge to the subspace with global optimum with the probability of 1 .

Theorem 1. Proof. According to the theory of HSAS/FFT, the direction of individuals toward optima is the maximum of gradient descent. If there is no gradient descent in the neighbourhood, individuals will stop moving. Therefore, the fitness of the population is not ascending that is $f(A(n+1)) \leq f(A(n))$. In consequence, there exists $f\left(a^{(n+1)}\right) \leq f\left(a^{(n)}\right)$, where $a^{(n)}$ presents the minimum of $n$-th $(n=1,2, \ldots, k)$ time iteration, $k$ is the maximum number of iteration and sufficiently large, $f\left(a^{(n)}\right)$ is the fitness of individual, $f(A(n))$ is the fitness of the population. It has $f\left(a^{(1)}\right) \geq f\left(a^{(2)}\right) \geq \cdots \geq f\left(a^{(n)}\right) \geq \cdots$, thus $\left\{f\left(a^{(n)}\right)\right\}$ is monotonic sequence. Definition 1 shows that the optimum problems exist global optimum, and so mean of sampling points in the subspace $\left\{f\left(a^{(n)}\right)\right\}$ is bounded. Therefore, $\left\{f\left(a^{(n)}\right)\right\}$ is monotonic, no ascending and bounded sequence.

Theorem 2. Proof. According to Theorem 1, $\left\{f\left(a^{(n)}\right)\right\}$ is monotonic, non-ascending and bounded sequence, and then $\left\{f\left(a^{(n)}\right)\right\}$ must possess a limit with Lemmas 1 and 2. If $\lim _{n \rightarrow+\infty} f\left(a^{(n)}\right)=f\left(a^{*}\right)$ exists and $a^{*}$ is the subspace with global optimum, and then $\left\{f\left(a^{(n)}\right)\right\}$ is globally convergent. $\lim _{n \rightarrow+\infty} f\left(a^{(n)}\right)=f\left(a^{*}\right)$ is random event, as $\left\{f\left(a^{(n)}\right)\right\}$ is stochastic sequence. So when $P\left(\lim _{n \rightarrow+\infty} f\left(a^{(n)}\right)=f\left(a^{*}\right)\right)=1$ is true, and then the sequence of $\left\{f\left(a^{(n)}\right)\right\}$ can converge with the probability of 1 . It has been proved as follows.

For $\forall \varepsilon \geq 0$, there exists $T_{\varepsilon}=\left\{a \in D, f(a)-f\left(a^{*}\right)<\varepsilon\right\}$ and the monotonic, non-ascending and bounded sequence $\left\{f\left(a^{(n)}\right)\right\}$ which is $f\left(a^{(1)}\right) \geq f\left(a^{(2)}\right) \geq \cdots \geq f\left(a^{(n)}\right) \geq \cdots$. Let $f\left(a^{(1)}\right) \geq f\left(a^{(2)}\right) \geq \cdots \geq f\left(a^{(n)}\right) \geq \cdots$ subtract $f\left(a^{*}\right)$, so $f\left(a^{(1)}\right)-f\left(a^{*}\right) \geq f\left(a^{(2)}\right)-$ $f\left(a^{*}\right) \geq \cdots \geq f\left(a^{(n)}\right)-f\left(a^{*}\right) \geq \cdots$. Let $C=\left\{a^{(i)} \in T_{\varepsilon}, i \in(1,2, \ldots k)\right\}$ represent the iterated sequence which stuck into the neighborhood $T_{\varepsilon}$ for $i-t h$ times. Thus, there exists $C_{1} \subseteq C_{2} \subseteq$
$\cdots \subseteq C_{i} \subseteq \cdots$ for $\varepsilon$, thereby the inequality $P\left(C_{1}\right) \leq P\left(C_{2}\right) \leq \cdots \leq P\left(C_{i}\right) \leq \cdots$ is true. And as $0 \leq$ $P\left(C_{1}\right) \leq 1, \lim _{i \rightarrow+\infty} P\left(C_{i}\right)$ is existent.

The stochastic sequence is presented by:

$$
\zeta_{i}=\left\{\begin{array}{ll}
1, & i \text { th iteration drop into } \mathrm{T}_{\varepsilon}  \tag{1}\\
0, & i \text { th iteration do not drop into } \mathrm{T}_{\varepsilon}
\end{array} \quad i=1,2, \cdots, k\right.
$$

and $C_{i}=\left\{\zeta_{i}=1\right\}$. Let $P\left\{\zeta_{i}=1\right\}=q_{i}, P\left\{\zeta_{i}=0\right\}=1-q_{i}$. Therefore, $B_{i}=\frac{1}{i} \sum_{j=1}^{i} \zeta_{j}$, there exists:

$$
\begin{gather*}
E\left(B_{i}\right)=\frac{1}{i} \sum_{j=1}^{i} q_{j}, \quad i=1,2, \cdots, k  \tag{2}\\
D\left(B_{i}\right)=\frac{1}{i^{2}} \sum_{j=1}^{i} D\left(\zeta_{i}\right)=\frac{1}{i^{2}} \sum_{j=1}^{i} q_{j}\left(1-q_{j}\right), i=1,2, \cdots, k \tag{3}
\end{gather*}
$$

where $E\left(B_{i}\right), D\left(B_{i}\right)$ are the expected value and standard deviation of the sequence $B_{i}(i=$ $1,2, \cdots, k)$, respectively. And due to Chebyshev inequality, there exists:

$$
\begin{equation*}
P\left\{\left|B_{i}-E\left(B_{i}\right)<\varepsilon\right|\right\} \geq 1-\frac{D\left(B_{i}\right)}{\varepsilon^{2}} \tag{4}
\end{equation*}
$$

and $q_{j}\left(1-q_{j}\right) \leq \frac{1}{4}$ is true in equation (9), therefore,

$$
\begin{gather*}
P\left\{\left|B_{i}-E\left(B_{i}\right)\right|<\varepsilon\right\} \geq 1-\frac{1}{4 i \varepsilon^{2}}  \tag{5}\\
\lim _{i \rightarrow+\infty} P\left\{\left|B_{i}-E\left(B_{i}\right)\right|<\varepsilon\right\}=1 \tag{6}
\end{gather*}
$$

and because of $\zeta_{i}=i B_{i}-(i-1) B_{i-1}, i=1,2, \cdots, k$, there exists:

$$
\begin{equation*}
\lim _{i \rightarrow+\infty} P\left\{\left|\zeta_{i}-E\left(\zeta_{i}\right)\right|<\varepsilon\right\}=1 \tag{7}
\end{equation*}
$$

The sequence of stochastic variables $\zeta_{i}(i=1,2, \cdots, k)$ converges with the probability, so that the sequence of stochastic event $B_{i}(i=1,2, \cdots, k)$ also converges with the probability, that is $\lim _{i \rightarrow+\infty} P\left\{B_{i}\right\}=1$. Therefore, there exists:

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} P\left\{\left|f(A(n))-f\left(A^{*}\right)\right|<\varepsilon\right\}=1 \tag{8}
\end{equation*}
$$

For $\forall \varepsilon \geq 0$, when $\varepsilon$ tend to very small, that is:

$$
\begin{gather*}
\lim _{\varepsilon \rightarrow 0}\left|f\left(a^{(n)}\right)-f\left(a^{*}\right)\right|=0  \tag{9}\\
\lim _{\varepsilon \rightarrow 0} f\left(a^{(n)}\right)=f\left(a^{*}\right) \tag{10}
\end{gather*}
$$

Thus,

$$
\begin{equation*}
\lim _{n \rightarrow+\infty} P\left\{f\left(a^{(n)}\right)=f\left(a^{*}\right)\right\}=1 \tag{11}
\end{equation*}
$$

Namely, the sequence $\left\{f\left(a^{(n)}\right)\right\}$ can converge to the global optimum with the probability of 1.

## S2. Description of CEC2017 benchmark set

To assess the performance of the proposed algorithm on single objective real-parameter numerical optimization, thirty benchmark functions on the CEC 2017 test suite are employed in the following experiments. A brief description of these functions with different characteristics which used to conduct the performance analysis of the proposed algorithms is listed in Table 1. $f_{1}-f_{3}$ are unimodal functions. Simple Multimodal Functions consists of seven functions from $f_{4}-f_{10}$ are multimodal functions with a lot of local optima, so it is easy to trap into local optima. Considering that in the real-world optimization problems, different subcomponents of the variables may have
different properties, therefore functions from $f_{11}-f_{20}$ are proposed as the hybrid functions. The remaining functions of the test suite are composition functions. All these benchmark functions are evaluated as the minimization problems. More details about the definition of these functions can be found in the literature (Awad et al. 2016).

Table 1. Summary of the CEC 2017 test functions.

| Class | No. | Functions | $F_{i}^{*}=F_{i}\left(x^{*}\right)$ |
| :---: | :---: | :---: | :---: |
| Unimodal <br> Functions | 1 | Shifted and Rotated Bent Cigar Function | 100 |
|  | 2 | Shifted and Rotated Sum of Different Power Function | 200 |
|  | 3 | Shifted and Rotated Zakharov Function | 300 |

|  | 30 | Composition Function $10(N=3)$ | 3000 |
| Search Range: $[-100,100]^{D}$ |  |  |  |

According to the guidelines requirements of CEC2017 benchmark competition, all experimental algorithms are performed. More specifically, when the solution found by the experimental algorithm is smaller than $10-8$, the error is set to 0 . The dimension number $(D)$ of these test functions is set to $10,30,50$, and 100 , respectively. The maximum evaluated times is set to $D \times 10,000$ on each run. Each problem is evaluated at 51 times. Moreover, five statistical metrics are designed, such as Best, Worse, Median, Mean, and Standard deviation (Std.) (Awad et al. 2016). These metrics can be employed to evaluate the solving performance of these various algorithms.

## S3. Parameters analysis

The parameter setting plays an important part in the performance of HSAS/FFT. In HSAS/FFT, there are five crucial parameters: reduction factor $W_{T}$, population size $N$, population convergence threshold $C$, reinitializing probability $P_{r}$, and number of samples $S$. To analyse the influence of each parameter in HSAS/FFT, the Taguchi method (Montgomery 2008) of design for the experiments is adopted. In the experiment, the CEC2017 benchmark functions (Awad et al. 2016) is adopted to calibrate the proposed algorithm. The various values of $W_{T}, N, C, P_{r}$ and $S$ are listed in Table 2. The parameter combinations and average error values yielded by HSAS/FFT are listed in Table 3. Table 4 lists each parameter's significance rank according to Table 3. Meanwhile, the trend of the parameters is described in Figure 1.

From Table 4 it is observed that $W_{T}$ is the most significant one among them, which implies that $W_{T}$ is important to HSAS/FFT. The large $W_{T}$ can improve the solution accuracy. But too large $W_{T}$ will always need oversize computational budget. $N$ ranks the second place, which illustrates
that it is also an important factor in HSAS/FFT. A small $N$ would cause the population easily fall into the local optimum. A large $N$ can lead the algorithm to search in the global space, but also will take a huge time to evaluate the population. $C$ ranks the third place. A large $C$ represents a strict criterion of population convergence. But it will slow down the evolutionary speed. From Figure 1, the change trend of $P_{r}$ and $S$ is relatively stable, which means it has slight effect on the performance of HSAS/FFT. A small $P_{r}$ and $S$ can improve the convergence rate. A large $P_{r}$ and $S$ can lead the algorithm search in the global space to improve the quality of the solution. According to the results of Taguchi method, the parameters in HSAS/FFT are suggested as follows: $W_{T}=1 / 3$, $N=10, C=80 \%, P_{r}=0.05$ and $S=20$.

Table 2. The parameters for different levels.

| Parameters | Levels |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 |
| $W_{T}$ | $1 / 10$ | $1 / 5$ | $1 / 3$ | $1 / 2$ |
| $N$ | 5 | 10 | 50 | 100 |
| $C$ | $60 \%$ | $70 \%$ | $80 \%$ | $90 \%$ |
| $P_{r}$ | 0.005 | 0.01 | 0.05 | 0.1 |
| $S$ | 10 | 20 | 50 | 100 |

Table 3. Parameter combinations and average error values.

| No. | Parameter combinations |  |  |  |  | Average error values |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $W_{T}$ | $N$ | C | $P_{r}$ | $S$ |  |
| 1 | 1/10 | 5 | 60\% | 0.005 | 10 | 9703.61 |
| 2 | 1/10 | 10 | 70\% | 0.010 | 20 | 7395.42 |

## S4. Statistical results of the HSAS/FFT

In this section, the proposed algorithm is run independently 51 times, and five statistical metrics are calculated, such as Best, Worse, Median, Mean, and Std. (Awad et al. 2016). These metrics can be used to analyse the performance of the proposed algorithm. The maximum number of objective function evaluations is $D \times 10,000$. Table 5 and Table 6 show the computational results of the proposed algorithm in solving the CEC2017 competition on real-parameter optimization problems for dimension 10, 30, 50, and 100. Each column shows Best, Worse, Median, Mean, and Std. of the error value between the true optimal value and the best fitness values found by the algorithm in each run. Max and Min represent the maximum and minimum fitness values of the algorithm over the 51 runs, respectively. Median denotes the median of the fitness values over the 51 runs. Mean represents the average value of the result fitness values over the 51 runs. Std. stands for standard deviation. It is worth noting that the error values smaller than $1.00 \mathrm{E}-08$ has been set as zero.

From the results obtained in Table 5 for dimension 10, and 30, the HSAS/FFT could perform good results in unimodal problems from $f_{1}$ to $f_{3}$. While for multimodal function, the optimal solution is still available on $f_{4}, f_{6}, f_{9}$ in dimension 10 , and available on $f_{6}, f_{9}$ in dimension 30 .

For $f_{5}, f_{7}, f_{8}$, the error value is still smaller than $1.00 \mathrm{E}-01$ in dimension 10 . While for all the hybrid functions, the error value is still small than $1.00 \mathrm{E}-01$ on $f_{15}, f_{16}, f_{18}, f_{19}$ and $f_{20}$ for dimension 10. As for the remaining composition functions, the best error value is larger than $1.00 \mathrm{E}+02$ except $f_{21}, f_{22}, f_{24}$ for dimension 10 .

Similarly, Table 6 for dimension 50, and 100 presents the statistical results. From the comparisons regarding the unimodal problems, the proposed algorithm performs good results on $f_{1}$ for dimension 50 and 100. For multimodal functions, the error value of the proposed algorithm is smaller than $1.00 \mathrm{E}-01$ on $f_{6}, f_{9}$. While for all the hybrid functions, the error value is still small than $1.00 \mathrm{E}+03$ except $f_{12}, f_{16}, f_{17}$ for dimension 50 and small than $1.00 \mathrm{E}+04$ except $f_{12}$, $f_{16}, f_{17}, f_{20}$ for dimension 100. As for the remaining composition functions, the best error value is still less than $1.00 \mathrm{E}+04$ except $f_{30}$ in dimension 50 .

In summary, the proposed algorithm has obtained good results on the most of functions from low dimension to high dimension. Compared with solving unimodal functions, the proposed algorithm is difficult to solve multimodal functions, hybrid functions, and composition functions.

Table 5. The statistical results of HSAS/FFT on the CEC2017 benchmarks for $D=10,30$
dimensions.

| Func. | 10D |  |  |  |  | 30D |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Best | Worst | Median | Mean | Std. | Best | Worst | Median | Mean | Std. |

## S5. Comparison of HSAS/FFT with some state-of-the-art algorithms under the CEC2017

 evaluation criteriaThe CEC2017 evaluation criteria (Awad et al. 2016) is adopted to analyse and compare the HSAS/FFT, jSO, RB-IPOP-CMA-ES, PPSO, and DE. The evaluation method for each algorithm is based on a score of 100. For detailed evaluation criteria, please refer to (Awad et al. 2016).

F2 has been excluded because it shows unstable behaviour especially for higher dimensions, and significant performance variations for the same algorithm implemented in Matlab, C. The final ranking result is shown in Table 7. HSAS/FFT is ranked the second of the comparative algorithms according to the results in Table 7.

Table 7. Ranking of HSAS/FFT, jSO, RB-IPOP-CMA-ES, PPSO, and DE obtained through the evaluation criteria in CEC2017.

| Algorithms | Score1 | Score2 | Final Score | Rank |
| :---: | :---: | :---: | :---: | :---: |
| HSAS/FFT | $4.7253 \mathrm{E}+01$ | $3.2479 \mathrm{E}+01$ | $7.9732 \mathrm{E}+01$ | 2 |
| jSO | $5.0000 \mathrm{E}+01$ | $5.0000 \mathrm{E}+01$ | $1.0000 \mathrm{E}+02$ | 1 |
| RB-IPOP-CMA-ES | $3.8162 \mathrm{E}+00$ | $3.2386 \mathrm{E}+01$ | $3.6203 \mathrm{E}+01$ | 4 |
| PPSO | $3.9494 \mathrm{E}+00$ | $3.1405 \mathrm{E}+01$ | $3.5354 \mathrm{E}+01$ | 5 |
| DE | $1.5719 \mathrm{E}+01$ | $3.1579 \mathrm{E}+01$ | $4.7298 \mathrm{E}+01$ | 3 |

In summary, the statistical analysis of the results obtained by the algorithms in the comparative study showed that the jSO is really the best because it outperformed the results of all the other significantly by solving the CEC2017 benchmark functions of all observed dimensions. Even though HSAS/FFT cannot get the best results on some test problems, it can get the suboptimal results compared with all experimental algorithms. The proposed HSAS/FFT is superior to RB-IPOP-CMA-ES, PPSO, and DE on the most of benchmark problems with a different dimension. Compared with other methods, HSAS/FFT can get the best results on the unimodal and hybrid functions with the different dimensions. On the rest of test problems, the proposed algorithm still
keeps the stable solving performance. Meanwhile, the convergence rate of HSAS/FFT is much better than other algorithms in most of the functions in the early stage of the search, which benefited from fast Fourier transform and search space segmentation. More specifically, the correct reduction of search space accelerates the convergence process.

## S6. HSAS/FFT time complexity

This subsection deal with an analysis of the HSAS/FFT time complexity as defined in (Awad et al. 2016). The dunning time obtained by evaluating the benchmark function $f_{18}$, is compared with a running time of the test program presented in Algorithm 3. The experiments are run in Windows Server 2012 R2 under the hardware environment of Intel Core i7-2760QM CPU @ 2.40 GHz processor and 8.0 GB of RAM. The proposed algorithm is implemented using $\mathrm{C}++$ programming language.

```
Algorithm 3. The test program.
    Initialize: \(x=0.55\)
    Start
        For \(k=1: D\)
                    \(x=x+x ;\)
                    \(x=x / 2 ; x=x \times x ; x=\sqrt{x} ;\)
                    \(x=\log (x) ; x=\exp (x)\);
                    \(x=x /(x+2))\)
        End for
        End
```

The computing time of the test program is denoted as $T 0$. Variable $T 1$ is the time required for evaluating the benchmark function $f_{18}$ and variable $T 2$ the time of HSAS/FFT execution for function $f_{18}$ within 200,000 evaluations for each dimension. Variable $\widehat{T 2}$ is an average of $T 2$ values obtained in five independent runs. Table 8 shows the algorithm complexities relationship with dimension. The computational complexity of the algorithm HSAS/FFT is reflected by the measured
and calculated variables $T 0, T 1, \widehat{T 2}$ and $(\widehat{T 2}-T 1) / T 0$ for each of the observed dimension $D=$ $\{10,30,50,100\}$. Obviously, this calculation is independent of the computing system and programming language in which the measured algorithm is implemented. According to Table 8, it is easy to conclude that more computational cost is required with the increasing number of dimensions for the benchmark functions.

Table 8. The computational complexity of the algorithm HSAS/FFT (all times are in seconds).

| $D$ | $T 0$ | $T 1$ | $\widehat{T 2}$ | $(\widehat{T 2}-T 1) / T 0$ |
| :---: | :---: | :---: | :---: | :---: |
| 10 |  | 0.270703 | 2.536710 | 15.360468 |
| 30 | 0.147522 | 0.914563 | 6.916988 | 40.688338 |
| 50 |  | 1.995140 | 11.897618 | 67.125432 |
| 100 |  | 6.741860 | 27.265260 | 139.120945 |
